Outline

- 1 Introduction
- 2 A Case Study: Concurrent Protein Structure Prediction
- 3 An Higher Point of View
- 4 Work, Work, Work!

Overview

- Main subject of my research: **concurrent optimization systems**.
- Starting point: **Protein Structure Prediction** — concurrent predictor (CCP/Multi-Agent based).
- Need of a general framework. Development of a **CCP-based language**.
- Now working on analysis techniques.

Some biology: Proteins

- Proteins are fundamental biological molecules, made from aminoacids (**primary structure**).
 - Their functionality derives from their peculiar 3D structure (**native or tertiary structure**).
 - It is supposed to be the state of **minimum free energy**.
-
- The **protein structure prediction problem** is the problem of identifying the 3D fold of a protein, given its primary structure.
 - It is an **optimization problem**.

Designing a Concurrent Optimization Strategy

- Idea: **mimic concurrency** of natural processes.
- Every aminoacid is an **independent process/agent**:
 - **communicating** its position to other agents
 - **moving** in the space using a Monte Carlo criterion
- The overall heuristic used is a **simulated annealing**.
- Communications are optimized, focusing on neighbors.

Improving the Framework

- The space exploration is slow. Improved by **making big jumps** (performed by a dedicated agent).
- External information (e.g. secondary structure predictors) can be exploited through cooperation: **agents cooperate to reach suitable configurations** (modification of the energy function)

Results up to Now

- The energy model used is too **coarse**, and must be improved.
- Using cooperation, decent prediction can be obtained in reasonable time.

The Messy Land of Concurrent Metaheuristics

- There are several strategies (**metaheuristics**) in literature for parallel/concurrent optimization.
- They are **hardly comparable** (test depend on the low-level implementation), and they even use different linguistic metaphors and notations.
- We felt the need of a **common basis** where to describe and analyze such strategies.
- The first step is the identification of a **suitable language** in which defining them.

Features of the Language

We wanted to model distributed optimization metaheuristics.
We needed:

- **constraints** → *constraint based language*;
- **concurrency** → *CCP*;
- **distribution** → *distributed CCP*;
- **probabilities** → *probabilistic and distributed CCP*;

Distributing CCP

- CCP is difficult to distribute: communication is performed through globally shared variables.
- Idea: **fragmenting the constraint store** in independent sets (nodes), and exchanging information between them through *communication channels*.
- In each node, computations evolve like in CCP.
- Communication is **synchronous**.
- There are **several message types**: **constraint templates**, **agent templates** and **channels** (which work like in π -calculus).
- There is also the possibility of **remotely linking variables** belonging to different nodes, so that information flows automatically among them.

Adding Probabilities to CCP

- We add probabilities to the language, in order to **reason quantitatively** on computations.
- The operational semantic of the language is given by a **labeled transition relation**, where labels are **probabilities** associated with transitions.
- Non-deterministic choice, local and global parallel operators are all weighted by a (discrete) probability distribution.
- The model of **time is discrete**
- Every computational trace has a probability associated to it, and the output of the program is a p.d. over the constraint store.

Extending the Protein Predictor

- Using a more detailed energy model.
- Implementing a true parallel version in MPI.
- Enhancing the exploration of the state space by using more complex internal representation of aminoacids.
- Refining the metaheuristics
- Enhancing the cooperative features.
- Implement it in our language.

Extending the Language

- We have an implementation (meta-interpreter in SICStus prolog), for a subset of the language.
- We plan to extend it to the full language, and writing it in LINDA.
- We want to design a continuous time version of the language, using rates instead of probabilities.
- We want to make the network topology more dynamic.

Analyzing the Programs

- We want to reason on properties like convergence, average execution time, average quality of solutions found.
- We want to compare different methods/heuristics w.r.t. the previous properties.
- We need to explore the transition graph of the model: **probabilistic model checking**.
- We need to develop a version for CCP and its extensions.
- We can use the language and the analysis tools also for creating an high level framework to model and study biological processes.

The End

THANKS FOR THE ATTENTION!
